

## Physics 151 Class Exercise: Calorimetry II

1. A kilogram of a substance gives a T-versus-Q Graph as shown below.
- What are the melting and boiling points?
  - What are the specific heats of the substance during its various phases ?
  - What are the latent heats of the substance at the various phase changes?

Melting Point =  $110^{\circ}\text{C}$

Boiling Point =  $140^{\circ}\text{C}$

$$\text{Specific Heat as Solid} = c = \frac{Q}{m\Delta T} = \frac{(0.1 \times 10^4 \text{ J})}{(1 \text{ kg})(10^{\circ}\text{C})} = 100 \frac{\text{J}}{\text{kg} \cdot ^{\circ}\text{C}}$$

$$\text{Specific Heat as Liquid} = c = \frac{Q}{m\Delta T} = \frac{(0.6 \times 10^4 \text{ J})}{(1 \text{ kg})(30^{\circ}\text{C})} = 200 \frac{\text{J}}{\text{kg} \cdot ^{\circ}\text{C}}$$

$$\text{Specific Heat as Gas} = c = \frac{Q}{m\Delta T} = \frac{(0.2 \times 10^4 \text{ J})}{(1 \text{ kg})(20^{\circ}\text{C})} = 100 \frac{\text{J}}{\text{kg} \cdot ^{\circ}\text{C}}$$

$$\text{Latent Heat of Fusion} = L_f = \frac{Q}{m} = \frac{(0.4 \times 10^4 \text{ J})}{(1 \text{ kg})} = 4000 \frac{\text{J}}{\text{kg}}$$

$$\text{Latent Heat of Vaporization} = L_v = \frac{Q}{m} = \frac{(0.6 \times 10^4 \text{ J})}{(1 \text{ kg})} = 6000 \frac{\text{J}}{\text{kg}}$$

2. A 155-g aluminum cylinder is removed from a liquid nitrogen bath, where it has been cooled to  $-196\text{ }^{\circ}\text{C}$ . The cylinder is immediately placed in an insulated cup containing 80.0 g of water at  $15.0\text{ }^{\circ}\text{C}$ . What is the equilibrium temperature of this system? If your answer is  $0\text{ }^{\circ}\text{C}$ , determine the amount of water that has frozen. The average specific heat of aluminum over this temperature range is  $653\text{ J}/(\text{kg}\cdot\text{K})$ .

Assume that  $T_f = 0$ .

$$\begin{aligned} Q_{\text{Al}} &= \text{heat gained by aluminum} \\ &= m_{\text{Al}}c_{\text{Al}}(T_f - T_{\text{Al},i}) \\ &= (0.155\text{ kg})\left(653\frac{\text{J}}{\text{kg}\cdot\text{C}^{\circ}}\right)[0^{\circ}\text{C} - (-196^{\circ}\text{C})] \\ &= 19,838\text{ J} \end{aligned}$$

$$\begin{aligned} Q_{\text{wb}} &= \text{heat lost by water before it freezes} \\ &= m_{\text{w}}c_{\text{w}}\Delta T \\ &= (0.0800\text{ kg})\left(4186\frac{\text{J}}{\text{kg}\cdot\text{C}^{\circ}}\right)(15.0^{\circ}\text{C}) \\ &= 5023\text{ J} \end{aligned}$$

Since  $Q_{\text{Al}} > Q_{\text{wb}}$ , we know that  $T_f \leq 0^{\circ}\text{C}$ .

$$Q_{\text{F}} = \text{heat lost by } 0\text{ }^{\circ}\text{C} \text{ water during freezing} = m_{\text{w}}L_{\text{f}} = (0.0800\text{ kg})(33.5 \times 10^4\text{ J}) = 26,800\text{ J}$$

Since  $Q_{\text{Al}} < Q_{\text{wb}} + Q_{\text{wf}}$ , not all of the water freezes, so  $T_f = \boxed{0^{\circ}\text{C}}$ .

Let  $m_{\text{f}}$  = the mass of water that freezes.

$$\begin{aligned} Q_{\text{Al}} &= Q_{\text{wb}} + m_{\text{f}}L_{\text{f}} \\ m_{\text{f}} &= \frac{Q_{\text{Al}} - Q_{\text{wb}}}{L_{\text{f}}} \\ &= \frac{19,838\text{ J} - 5023\text{ J}}{33.5 \times 10^4\frac{\text{J}}{\text{kg}}} \\ &= \boxed{44.2\text{ g}} \end{aligned}$$
